# **Abstract**

The reduction of CO<sub>2</sub> to C<sub>2+</sub> products using photoelectrochemistry (PEC) is significant and highly challenging. However, systematic summaries on PEC CO<sub>2</sub> conversion into  $C_{2+}$  products are lacking. Therefore, this paper systematically reviews the current research status of the PEC CO<sub>2</sub> conversion for the preparation of  $C_{2+}$  products, including the pathways of  $C_{2+}$  products, the usage of catalysts and reactors, and methods for improving  $C_{2+}$  product selectivity. Besides, the deficiencies in current research are analyzed, and future developments are discussed.

**Keywords:** Photoelectrochemistry, C<sub>2+</sub> products, CO<sub>2</sub> conversion

# INTRODUCTION

The hazards of climate change to humans and the environment necessitate transitioning from our current fossil fuel economy to an economy based on renewable and carbon-neutral energy technologies. The urgency to reduce primary greenhouse gas (CO<sub>2</sub>) emissions while continuing to provide fuel for the growing global population remains one of the most significant technological challenges of our time. Photoelectrochemical technology not only maximizes the advantages of photocatalysis and electrocatalysis,

**Figure 1.** The role of light and electricity in photoelectrochemical CO<sub>2</sub> reduction and the number of publications on PEC CO<sub>2</sub> conversion were obtained using keyword search (photoelectric and CO<sub>2</sub>). Data was extracted from the Web of Science in May 2024. PEC: Photoelectrochemistry.

but their synergy also sparks a different kind of brilliance. Utilizing photoelectrochemistry (PEC) technology to convert  $CO_2$  into fuel represents a new, clean, and green approach to using  $CO_2^{[1\text{-}3]},$  $CO_2^{[1\text{-}3]},$  $CO_2^{[1\text{-}3]},$  which is increasingly attracting the interest of researchers [[Figure 1\]](#page-1-0). Similar to other types of catalysis, the PEC conversion of CO<sub>2</sub> also involves multiple-step processes, resulting in a wide range of products such as  $C<sub>1</sub>$ (CO, CH<sub>4</sub>, HCOOH, *etc.*) and C<sub>2+</sub> products (C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, CH<sub>3</sub>COOH, *etc.*). Currently, most reported CO<sub>2</sub> conversion products are  $C_1$  products because the generation of  $C_2$  products involves a C-C coupling process, which is more difficult to obtain than  $C_1$  products. But, compared with  $C_1$  products,  $C_2$  products have higher added value, and research on directly converting  $CO_2$  into  $C_{2+}$  products holds significant significance. To date, several review articles have covered the overall research status on PEC  $CO<sub>2</sub>$ conversion<sup>[\[1-](#page-11-0)[7\]](#page-11-2)</sup>, the influence of cocatalysts<sup>[[8-](#page-11-3)[10](#page-11-4)]</sup>, the design of the PEC cathodes<sup>[[11](#page-11-5)[-15\]](#page-11-6)</sup>, the impact of PEC parameters<sup>[\[16](#page-11-7)[,17\]](#page-11-8)</sup>, and the study of catalysts<sup>[\[18-](#page-11-9)[20](#page-11-10)]</sup>. However, no individual summaries have been on converting CO<sub>2</sub> into C<sub>2+</sub> products using the PEC technology. Hence, firstly, this paper aims to briefly introduce the basic principles of  $CO_2$  conversion into  $C_{2+}$  products. Secondly, it summarizes the catalysts and reactor types reported thus far for obtaining  $C_{2+}$  products. Thirdly, it emphasizes the design strategies of catalysts currently available for generating or enhancing  $C_{2+}$  selectivity. Finally, it concludes with a summary of the current work and prospects for future research.

# FUNDAMENTAL OF PHOTOELECTROCHEMICAL CO<sub>2</sub> REDUCTION

The PEC reduction of  $CO_2$  involves light absorption, charge carrier transfer,  $CO_2$  adsorption and activation, surface reactions, and product desorption. The energy input for PEC catalysis is provided by light and electricity. Light plays a role in generating high-energy photoelectrons for CO<sub>2</sub> reduction, generating photoelectric voltage to reduce energy consumption to some extent and lower economic costs, and producing heat to promote the progress of the reaction. Electricity plays a role in introducing an additional bias voltage to accelerate charge carrier separation and increase local charge density. By adjusting the bias voltage, the CO<sub>2</sub> reduction pathway can be altered to enhance selectivity.

Additionally, the supplementation of voltage can enable semiconductor materials that were originally not viable for photocatalytic CO<sub>2</sub> conversion to become feasible [[Figure 1](#page-1-0)]. The synergistic effects of light and

 $(2-4)$ 

electricity can effectively reduce the activation energy for CO<sub>2</sub> reduction, but the study of the photoelectric synergistic effect is still lacking<sup>[[21](#page-11-11),[22](#page-11-12)]</sup>. Furthermore, the contribution and distinction between photogenerated and voltage-provided electrons have not yet been reported.

Based on current reports, the mechanism for converting  $CO_2$  into  $C_{2+}$  involves first converting  $CO_2$  into  $°C$ intermediates, followed by the generation of various intermediates of  $C_{2+}$  products through C-C coupling and multi-proton-coupled electron transfer (PCET), as shown by the equations for different pathways (Route 1-6)<sup>[[23](#page-11-13)]</sup>. However, the competitive adsorption of  $H_{ad}$  and  $^{\circ}$ CO on monocomponent catalysts hinders the enhancement of PCET and C-C reaction kinetics. In order to break the linear scaling relationship between the adsorption of  $H_{ad}$ <sup>\*</sup>CO intermediates and improve water dissociation on auxiliary sites or  $CO_2$ to-CO production, tandem catalysts consisting of multicomponents have been developed. These catalysts can achieve higher coverage of  $H_{ad}$  and  $^{\circ}$ CO, which is more conducive to the generation of  $C_{2+}$  products. However, to our knowledge, while there are detailed reports on achieving  $C_{2+}$  products through serial pathways in the electrocatalytic conversion of  $CO_2^{[24]}$  $CO_2^{[24]}$  $CO_2^{[24]}$ , their application in the field of photoelectrocatalytic CO<sub>2</sub> conversion has not been observed.

# CATALYSTS AND REACTORS OF PHOTOELECTROCHEMICAL CO<sub>2</sub> UPGRADING TO  $\mathrm{C}_{\mathrm{2+}}$

Hitherto, catalyst research for the PEC conversion of  $CO<sub>2</sub>$  into  $C<sub>2+</sub>$  products is focused on photocathodes, primarily using Cu-based catalysts<sup>[[21](#page-11-11),[24](#page-11-14)[-29\]](#page-12-0)</sup> [\[Table 1\]](#page-4-0). Cu-based species have a high binding affinity for \*CO intermediates, making them active sites for  $CO<sub>2</sub>$  reduction and the generation of  $C<sub>2+</sub>$  chemical species. However, the high energy barriers associated with C-C coupling and PCET processes still pose challenges for Cu-based catalysts regarding high overpotential and low selectivity towards  $C_{2+}$  products. In addition to Cu-based catalysts, reasonable structural design of some non-Cu-based catalysts enables higher selectivity towards  $C_{2+}$  products. [Table 2](#page-5-0) lists the selectivity of some non-Cu-based catalysts in photoelectrocatalytic  $CO<sub>2</sub>$  conversion. It shows that the non-Cu-based catalysts are mainly composite materials, including TiO<sub>2</sub>, , ZnO, WO<sub>3</sub>, etc., with more negative potentials compared to Cu-based catalysts. Regardless of Cu-based or non-Cu-based catalysts, ethanol, acetic acid, and ethylene are the main  $C_{2+}$  products; the yield of  $C_{2+}$ products is relatively low (typically at the μmol level); the Faradaic efficiencies cover a wide range, and the faradaic efficiency for a single  $C_{2+}$  product can reach up to 80%. The selectivity of  $C_{2+}$  products is primarily enhanced by adjusting the synthesis process of materials, doping with heteroatoms, and compositing with other metals/metal oxides/non-metallic materials to alter the morphology, band structure, and local electron density of the electrode materials.

In addition to catalysts, the selection of reactors also significantly influences the generation of  $C_{2+}$  products. The light source, membrane characteristics, electrolyte, manufacturing materials, wall thickness, operational modes (batch or flow), heat exchange, phase requirements (gas-solid, liquid-solid, or gas-liquid-solid), CO<sub>2</sub> solubility, and flow characteristics of feed gases and electrolytes can affect catalytic performance<sup>[[54](#page-13-0)[,55\]](#page-13-1)</sup>. . Currently, reactors used for CO<sub>2</sub> PEC conversion are primarily modified from electrochemical CO<sub>2</sub> reduction reactors and can be divided into H-type and flow electrolysis cells [[Figure 2](#page-6-0)][[56](#page-13-2)[-58\]](#page-13-3). The H-type electrolysis cell is a relatively simple device that belongs to a batch reactor. It separates the anode and cathode using ion exchange membranes. However, its significant Ohmic resistance between the electrodes and limited  $CO_2$  solubility have hindered its development. The low current density (< 100 mA·cm<sup>-2</sup>) achieved in H-type cells does not meet industrial requirements. Furthermore, alkaline electrolytes are more conducive to suppressing H<sub>2</sub> reduction and enhancing C-C coupling. However, alkaline electrolytes are not feasible in aqueous  $\mathrm{CO}_2$  reduction conducted in H-type electrolysis cells. Nevertheless, the gas diffusion electrode (GDE) of the flow electrolysis cell separates the CO<sub>2</sub> flow field from the liquid electrolyte, allowing the use of high-concentration alkaline electrolytes.

The flow electrolysis cell is a continuous operation reactor where gases and electrolytes can be continuously supplied to the electrolytic cell. GDEs are used as the electrodes, which greatly overcome the limitations of CO<sub>2</sub> solubility. However, a certain distance between the anode and cathode still exists, resulting in significant Ohmic resistance. The membrane-electrode reactor integrates the anode, cathode, and membrane assembly, significantly reducing the distance between the electrodes and exhibiting improved catalytic performance. However, it lacks a reference electrode, making it challenging to obtain accurate working electrode potentials. Although membrane-electrode reactors have found wide applications in

electrochemical  $CO<sub>2</sub>$  reduction, there are few reports on their use in photoelectrochemical  $CO<sub>2</sub>$ conversion<sup>[\[37](#page-12-8)]</sup>. In addition, the state-of-the-art electrocatalytic CO<sub>2</sub> reduction performance achieved from flow electrolysis cells and membrane-electrode electrolyzers can almost produce CO and formic acid at industrial current densities. However, producing single high-value  $C_{2+}$  products, such as ethylene and ethanol, remains challenging. As for photoelectrochemical CO<sub>2</sub> reduction, the current densities used in the electrolytic cells have a significant gap compared to industrial current densities. It is worth mentioning that most of the recent research employs self-designed, assembled, or customized CO<sub>2</sub> photoelectrochemical reactors. No universally recognized standard exists for the configuration and operation of CO<sub>2</sub> electrolyzers. Different studies use distinct reactor structures, components, and catalysts, making it difficult to directly compare results and select optimal cathodic catalysts.

# STRATEGIES TO IMPROVE THE SELECTIVITY OF  $C_{2+}$  PRODUCTS

The photoelectrochemical conversion of  $CO<sub>2</sub>$  into  $C<sub>2+</sub>$  products is highly challenging. The entire process involves multiple aspects: absorption of light to obtain electron-hole pairs, followed by charge separation and transfer to the surface of the photocathode. At the same time,  $CO<sub>2</sub>$  adsorption is necessary for reducing CO<sub>2</sub> to form C<sub>1</sub> radicals and intermediates, and the stability of intermediates and C-C coupling is crucial. Moreover, the production of  $C_{2+}$  products requires more electrons compared to  $C_1$  products. These processes indicate that improving light absorption, enhancing CO<sub>2</sub> adsorption capacity, increasing charge separation and transfer efficiency, and constructing suitable active sites are essential for obtaining highcontent  $C_{2+}$  products. In addition, the reactor configuration, operating conditions, and electrode assembly also significantly influence catalytic performance. A continuous flow PEC reactor can produce more  $C_2$ - $C_3$ products compared to batch reactors<sup>[\[58\]](#page-13-3)</sup>, and selecting an appropriate voltage is beneficial for the generation of  $C_{2+}$  products<sup>[[17](#page-11-8)]</sup>; appropriate electrode assembly can increase  $CO_2$  adsorption, suppress hydrogen production, and facilitate  $C_{2+}$  product generation  $^{[40]}$  $^{[40]}$  $^{[40]}$ . However, there is a lack of research on the impact of reactor configuration, operating conditions, and electrode assembly on the obtained  $C_{2+}$  products. Besides,

Table 2. The selected non-Cu-based catalyst for photoelectrochemical conversion of CO<sub>2</sub> to C<sub>2+</sub>

FE: Faradaic efficiency; SCE: saturated calomel electrode; NS: nanosheet.

the current yield of  $C_{2+}$  products from  $CO_2$  conversion via photoelectrocatalysis is generally low (often below 50 µmol·cm<sup>-2</sup>·h<sup>-1</sup>), with correspondingly low current densities (below 10 mA·cm<sup>-2</sup>); many studies do not report  $\mathrm{CO}_2$  conversion rates or product yields<sup>[\[25\]](#page-12-25)</sup>. According to the reaction process, conversion rates and yields can be enhanced by adjusting reactor and reaction parameters (such as applying pressure) and modifying the properties of the photoelectrode. Specifically, improving light absorption capacity (through morphology control and elemental doping, *etc.*), enhancing charge carrier separation (via auxiliary metal addition and defect or heterojunction construction, *etc*.), and promoting surface reactions (by depositing a thin bilayer of Sustainion/Nafion, etc.) can contribute to these enhancements<sup>[[4\]](#page-11-15)</sup>. Therefore, this section mainly summarizes the research progress in improving the selectivity of  $C_{2+}$  products from four aspects: electrode material morphology design, adjustment of band structure, construction of heterojunctions, and design of active sites.

#### **Morphology**

The morphology significantly influences the selectivity of CO<sub>2</sub> PEC reduction products [[Figure 3\]](#page-7-0). Current research suggests that C2+ products can be acquired by constructing specific spatial structures. Wang *et al.* found that three-dimensional (3D) nanorod-shaped zinc oxide exhibited the optimal spatial environment compared to amorphous block-, mushroom-, and ball cactus-like structures, facilitating C-C coupling to produce  $C_2$  products (ethanol and acetic acid)<sup>[[44](#page-12-15)]</sup>. Furthermore, their research group discovered that porous PEC based on a 3D hierarchical structure of covalent organic frameworks (COFs) could effectively enhance

<span id="page-6-0"></span>

**Figure 2.** PEC reactor for CO<sub>2</sub> conversion (A) H-type cell (batch reactor)<sup>[[54](#page-13-0)]</sup>;(B) flow cell (continuous reactor). PEC: Photoelectrochemistry.

 $CO<sub>2</sub>$  adsorption and the rate of C-C coupling to generate  $C<sub>2+</sub>$  products<sup>[\[30\]](#page-12-1)</sup>. Hollow catalysts exhibited different selectivity on the inner and outer surfaces due to the increased collision probability of intermediates within the closed cavity, achieving a high selectivity of  $C_{2+}$  products (67.0%) on the inner surface<sup>[\[49\]](#page-12-20)</sup>. In addition, by simulating the morphology of thylakoids in plant cells, the Si@WO<sub>3</sub>-nanosheet (NS) catalyst with a 2D-3D structure is advantageous for achieving C-C coupling<sup>[\[53\]](#page-12-24)</sup>. .

#### **Band structure**

The band structure of electrode materials significantly influences light utilization and the types of CO<sub>2</sub> reduction products. A narrower band gap is beneficial for broadening the absorption range of light. In contrast, adjustable conduction band positions facilitate the control of product selectivity [[Figure 4](#page-7-1)]. The position of the conduction band is related to the reduction capability of the catalyst, playing a crucial role in the photoelectrocatalytic reduction of  $CO<sub>2</sub>$  and serving as a thermodynamic factor influencing the availability of  $C_{2+}$  products. Adjusting the conduction band to the appropriate position is beneficial for improving the acquisition of certain C<sub>2+</sub> products. Han *et al.* achieved improved selectivity of CO<sub>2</sub> reduction products by depositing metals such as Pd, Pt, Ni, Au, *etc.*, to modulate the conduction band potentials of the TiO<sub>2</sub>@ZnO/FTO<sup>[[45\]](#page-12-16)</sup>. Besides doping with metals, doping with non-metals can alter the conduction band

#### **Heterojunction**

The built-in electric field of heterojunctions facilitates carrier separation, accelerates charge transfer, and enhances the velocity of intermediates, resulting in a high probability of C-C coupling and, consequently, higher C<sub>2+</sub> product yields<sup>[[31](#page-12-2)[,53\]](#page-12-24)</sup> [[Figure 5](#page-8-0)]. Lu *et al*. constructed 0D/1D CuFeO2/CuO nanowire heterojunction arrays. They achieved a higher Faradaic efficiency (66.73%) for ethanol production at -0.6 V *vs*. Ag/AgCl, mainly attributed to the rapid separation of photogenerated electrons and holes in the heterojunction material and the transfer of electrons from  $CuFeO<sub>2</sub>$  to CuO, enabling highly content of  $C<sub>2+</sub>$  products (ethanol)<sup>[\[39\]](#page-12-10)</sup>. Xu et al. fabricated 2D TiO<sub>2</sub>/Ti<sub>3</sub>CN MXene heterojunctions, where the Pd@TOCN-200 photoelectrode exhibited the highest ethanol production rate (14  $\mu$ M·cm<sup>-2</sup>·h<sup>-1</sup>) due to the enhanced CO<sub>2</sub> adsorption and favorable C-C coupling environment provided by the 2D TiO<sub>2</sub>/Ti<sub>3</sub>CN heterojunction structure<sup>[[50\]](#page-12-21)</sup>. .

#### **Active site**

The active site is a critical part of catalytic reactions and directly determines the distribution of products. They change product distribution by affecting the adsorption strength of products and intermediates and promote the coupling of \*CO with \*CO by adjusting the local electron density gradient, facilitating C-C coupling, and enhancing the acquisition of  $C_{2+}$  products. In the PEC CO<sub>2</sub> reduction reaction, active sites composed of multimetallic species<sup>[[31](#page-12-2)[,33,](#page-12-4)[35](#page-12-6),[36](#page-12-7)[,52\]](#page-12-23)</sup>, oxygen vacancies/sulfur vacancies<sup>[\[34,](#page-12-5)[51](#page-12-22)]</sup>, certain specific functional groups (such as adjacent imine groups) $^{[47]}$  $^{[47]}$  $^{[47]}$ , and metal-nonmetal junctions $^{[38]}$  $^{[38]}$  $^{[38]}$  are favorable for CO $_2$ adsorption and C-C coupling, promoting the generation of  $C_{2+}$  products [[Figure 6](#page-9-0)]. Among them, Lu *et al.* doped Re into CuO and combined it with Ti nanotubes. Under solar light and -0.5 V *vs*. saturated calomel electrode (SCE) conditions, the product was almost entirely ethanol (1.9  $\mu$ M·h<sup>-1</sup>). The above results were attributed to high-valence rhenium as an active site for hydrogenation reactions. Its doping promoted the alcoholization process and facilitated C-C coupling<sup>[\[33\]](#page-12-4)</sup>. Zhou *et al.* adjusted the surface sulfur vacancies of Cu<sub>2</sub>ZnSnS<sub>4</sub> (CZTS)/CdS by annealing in different atmospheres, which were active sites for CO adsorption and followed C-C coupling. By rational tuning, they achieved higher ethanol selectivity<sup>[[34](#page-12-5)]</sup>. In addition,

Wang *et al.* introduced N into CuO to obtain Cu-N active components. These components possessed asymmetric d-p orbitals, which could reduce the activation energy of C-C coupling and induce local charge redistribution, thereby improving the material's conductivity. They achieved a 15.2% C, product selectivity in a water solution at 0.2 V vs. reversible hydrogen electrode (RHE)<sup>[[38](#page-12-9)]</sup>. .

# CONCLUSION AND PROSPECTS

Currently, research on PEC conversion of  $CO<sub>2</sub>$  to  $C<sub>2+</sub>$  products primarily focuses on developing photoelectrodes. The catalysts used are mainly Cu-based, and the major  $C_{2+}$  products obtained are ethanol, acetic acid, and ethylene. The involved reactors are predominantly flow reactors. Adjusting the catalyst morphology, band structure, and active sites can improve light absorption, enhance charge carrier transfer, strengthen CO<sub>2</sub>/CO<sup>\*</sup> adsorption, and provide a favorable C-C coupling environment, achieving high selectivity for  $C_{2+}$  products. Although some progress has been made in the research on PEC CO, conversion to  $C_{2+}$  products, there is currently limited reporting on products containing three or more carbon atoms. The types of catalysts used are also limited, and their yields are relatively low (typically at the level of μmol). The reactors used in studies are mostly self-designed, assembled, or customized. There is no recognized standard for the configuration and operation of CO<sub>2</sub> reactors, and it is difficult to selectively optimize cathode catalysts by directly comparing different research reports. The current density employed in electrolytic cells differs significantly from industrial-scale requirements, making industrialization challenging. The present reaction pathway is not yet clear, and there is still insufficient research on the specific reaction mechanisms involved in catalysts. Additionally, research on photoelectric synergies is lacking. Therefore, increasing efforts in reactor development and establishing design standards, exploring and developing cost-effective and high-performing catalysts, and conducting in-depth research to enhance catalytic performance and understand reaction mechanisms are the main directions for future investigations.

# **DECLARATIONS**
